Abstract

P.T. Alpha Jaya Manunggal Mandiri is a manufacturing company engaged in the furniture sector. In the spring bed production line, the time required to produce one spring bed requires a long machine set-up time and has many non-value-added operations. The first step is to minimize the spring bed production time and the distance of spring bed production by doing a waste analysis on the spring bed production process to identify the non-value activity and then remove that process. After that, create a new alternative layout with the S.L.P. method. The new alternative layout was created using process activity mapping to compare spring bed production time and distance from the old layout and the new alternative layout. Then, the set-up time on spring bed production is reduced by implementing a single SMED method. Then the last step is creating current value stream mapping and future value stream mapping. Then comparing the efficiency of current value stream mapping and future value stream mapping. From implementing SMED, removing the non-value-added activity, and implementing the new layout of spring bed production. With this implementation, the set-up time and the spring bed production process were reduced, reducing the set-up time on the spring bed production process and increasing the efficiency of value stream mapping.

Keywords

Value Stream Mapping, SMED, Process Activity Mapping, Waste Analysis, Layout

1. Introduction

P.T. Alpha Jaya Manunggal Mandiri is a company engaged in manufacturing established in 1998 located in Tangerang and engaged in the furniture industry. The company sells products in the form of spring beds and accessories such as bed frames, cots, mattress backs, and various other accessories. P.T. Alpha Jaya Manunggal Mandiri has an office on Jl. Arjuna Utara 10, West Jakarta and factory at Jl. Raya Kuta Bumi Km 6, Tangerang with an area of 5250 m². P.T. Alpha Jaya Manunggal Mandiri is a manufacturing company engaged in the furniture sector to produce cots, bedframes, spring beds, pillows, etc. The production process on each production line has a different production time. Making one spring bed requires a long machine set-up time and has many non-value-added operations in the spring bed production line. This condition causes waste in the spring beds production process, which is carried out in the form of waste of motion, waste of waiting, waste of transportation, etc. Based on the results of the research conducted at the spring beds production line, the following are the objectives in minimizing the set-up time and waste at the spring beds production line:

- a) Removing non-value-added operation on spring beds production process to minimize lead time and cycle time.
- b) Implementing SMED method to minimize the set-up time in the spring beds production process.
- c) Creating future value stream mapping on spring beds production line at P.T. Alpha Jaya Manunggal Mandiri.

2. Literature Review

2.1 Lean Manufacturing

Lean manufacturing is a methodology that focuses on minimizing waste within manufacturing systems while simultaneously maximizing productivity. Waste is defined as anything customers do not add value to and are unwilling to pay for (Salim et al., 2021).

2.2 Waste

In lean manufacturing, "waste" is defined as anything that doesn't add value to a product. "Value" in manufacturing is anything that a customer would be willing to pay. So, waste is any cost incurred in a process that does not benefit the customer (Chandra et al., 2021).

2.3 Time Study

A manufacturing time study is a structured process of directly observing and measuring human work using a timing device to establish the time required to complete the work by a qualified worker when working at a defined level of performance (Heap, 2015).

2.4 Set-up Time

Setting up a machine to change from one product to the next is the most significant part of the process for many manufacturing processes. Because it is a hassle, we try to do it as infrequently as possible, so we don't get good at it, and it takes a long time, and we need to run large batches to justify our long set-up times. Implementing a Lean Enterprise turns this theory on its head – we want to reduce inventory and make smaller batches, so we need to set-up more often and reduce the time it takes so our costs don't blow out. (George, 2012).

2.5 Lead Time

Manufacturing lead time refers to the duration between the start of processing an order and the time the production process is over. It is the time between processing the raw materials and the finished product. In some instances, it is always referred to as production lead time (Senapati, 2012).

2.6 Westinghouse Method

There is a scale of crisp numerical values for each factor in the usual Westinghouse method. In this study, a fuzzy rule-based approach is used to determine the performance values of the workers depending on the vague decision-making structure (Cevikcan, 2016). The Westinghouse rating method was created and published in 1927. The four components of this approach are skill, effort, circumstances, and consistency. There are six categories in the Westinghouse method: bad, fair, medium, good, excellent, and superskill. Additionally, each class has two additional degrees higher or lower (Cevikcan et al., 2012).

2.7 Allowance

Allowances in time study can be defined as the extra time figures which are to be added to the basic time of an operation to account for personnel desires, delays, fatigue of operators, any particular situation and the policies of the firm or organization. The standard time of a job is obtained by adding various allowances to the basic or normal time of the job (Souraj et al., 2010).

2.8 SMED (Single-Minute Exchange of Dies)

SMED is an acronym for the lean production method – SMED. Developed by Shigeo Shingo, a Japanese Industrial Engineer, the methodology provides an efficient and timely transfer from one product to the next in a manufacturing process (Tampubolon et al., 2021). Equipment setup times can be shortened by using the theory and methods known as SMED. The goal of SMED is to complete setup times in fewer than ten minutes, or a single digit in terms of minutes. Manufacturing big quantities allowed for the lowest feasible proportion of idle time per unit produced, which was the best strategy to reduce the cost of idle machines during setup operations prior to the introduction of the SMED technique. The ideal quantity of each manufacturing lot was attained, when the costs of inventory were equal to the expenses of idle equipment during the changeover of tools (Min and Pheng., 2007).

2.9 Value Stream Mapping

Value stream mapping is a lean management tool that helps visualize the steps needed from product creation to delivering it to the end customer. As with other business process mapping methods, it helps with introspection (understanding your business better) and analysis and process improvement (Hines et al., 1997). The mapping (VSM) process involves mapping the information and material flows necessary to coordinate the tasks carried out by manufacturers, suppliers, and distributors in order to deliver products to customers. A current state map was initially created, from which the cause of waste was found and the opportunity for applying various lean techniques was discovered (Sundar et al., 2014).

2.10 Process Activity Mapping

Process mapping is the graphical representation with illustrative descriptions of how things get done. It helps the participants visualise the process's details closely and guides decision making. One can identify the major areas of strengths and weaknesses in the existing process, such as individual steps' contribution to the process. Further, it helps to reduce the cycle times and defects in the process and enhances its productivity (Amrina, 2020).

2.11 Layout Planning

Layout planning is the process of making decisions about how to physically organize all of the resources that are accessible in a production system and take up space inside a facility. This kind of layout decision is made while developing a new facility or making any adjustments to the resources, such as moving a machine or hiring a new employee. Layout planning may also be done when a facility is expanded or when space is reduced. Layout planning is one of the most important aspects of Lean manufacturing. In some cases, it would be one of the solutions introduced in the Improve phase of DMAIC methodologies in lean six sigma projects (Gozali et al., 2020).

3. Methods

The methods of minimizing the waste and set-up time at the spring beds production line are formed into a flowchart. The methodology flowchart for reducing the waste and set-up time at the spring beds production line can be seen in Figure 1.

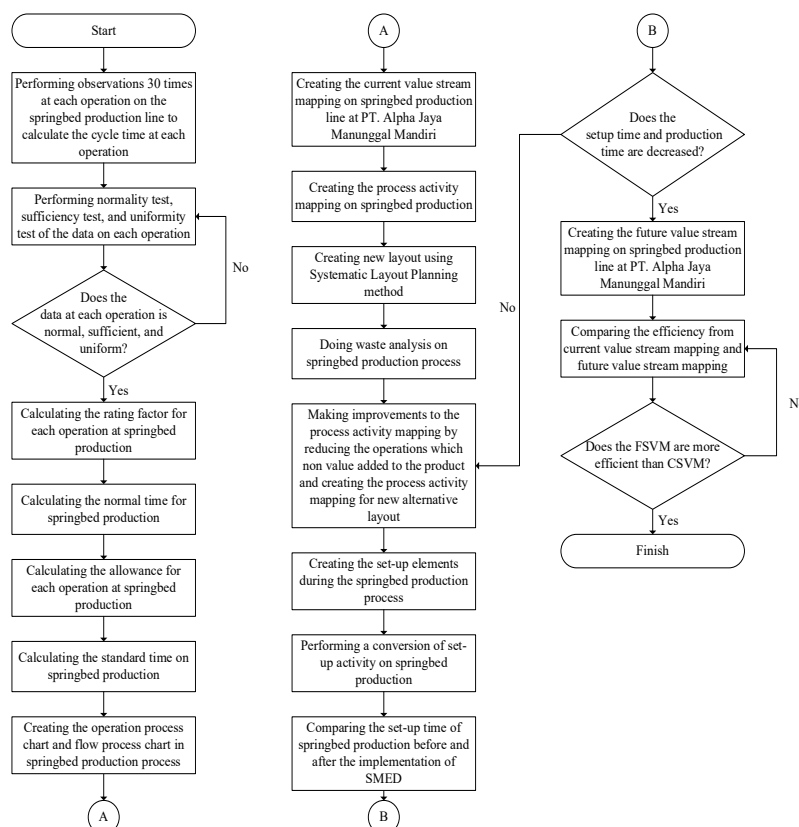

Figure 1. Flowchart Minimizing Waste and Set-up Time at Spring beds Production Line

4. Data Collection

4.1 Process Activity Mapping

Every activity in the spring beds production process is described and recorded in process activity mapping. Process activity mapping for spring bed products can be seen in Table 1.

Table 1. Process Activity Mapping

Process	Activity Description	Machine/ Tool	Distance (m)	Time (seconds)	Number of Workers	O	I	T	D	S
Springbed Frame Production Station	To the raw material storage	Carlift	2	45	1					
	Searching raw material		1.5	15	1					
	Taking the raw material to the springbed frame production making station		16	225	1

Storage	Storage Springbed Product	Walking Pallet	0	50	1					
Total			84.5	9410		26	3	11	0	1

4.3 Waste Analysis

Waste that occurs on the production floor is based on direct observations in the field. The waste that appears on the production floor is waste of transportation, waste of inventory, waste of motion, waste of waiting, and waste of defects from all 7 wastes. Waste that occurs on the production floor is categorized into 3 categories, namely Value Added (V.A.), Non-Value-Added (N.V.A.), and Necessary Non-Value-Added (NNVA). Waste analysis can be seen in Table 2.

Table 2. Waste Analysis

Process	Activity Description	VANVA/ NNVA	Waste							
			T	I	M	W	O	O	D	
Springbed Frame Production Station	To the raw material storage	NNVA								
	Searching raw material	NVA								
	Taking the raw material to the springbed frame production making station	NNVA								
	Putting the raw material to the spring coiling machine	NNVA								
	Setup spring coiling machine	NNVA								
	Spring coiling process	VA								
	Inspection of number and uniformity of spring size	NNVA								
	Moving spring to the pocket assembly machine	NNVA

Total	Springbed storage	NVA	13	1	22	5	0	0	0	0

4.4 Initial Layout

The initial layout of the P.T. Alpha Jaya Manunggal Mandiri factory can be seen in Figure 2.

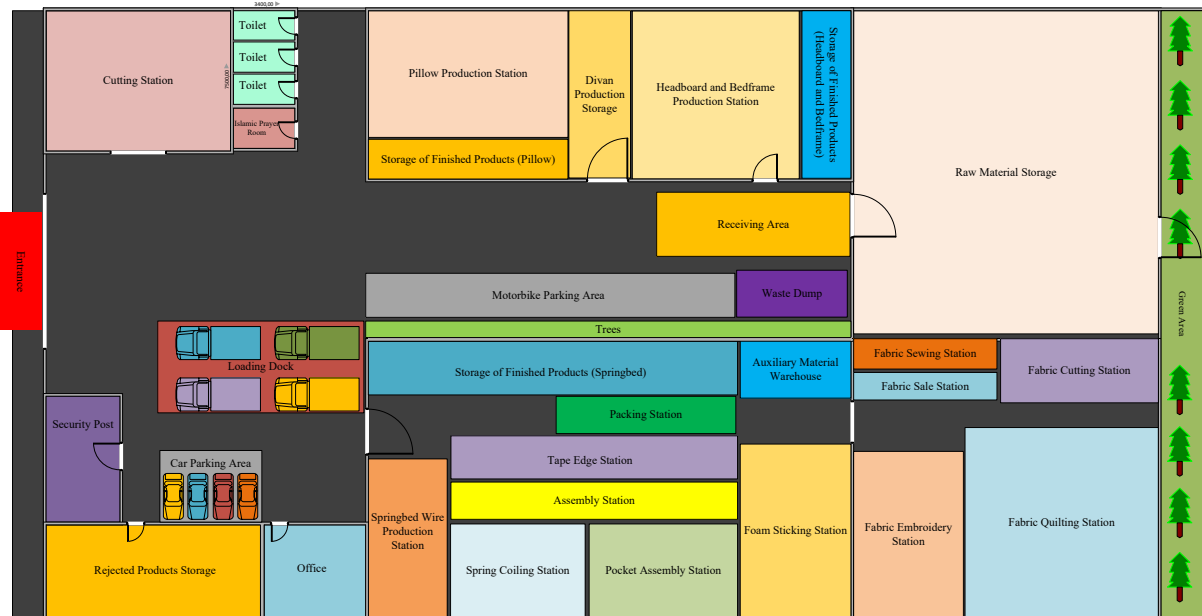

Figure 2. Initial Layout PT. Alpha Jaya Manunggal Mandiri Factory

4.5 Alternative Layout

From the initial layout of the P.T. Alpha Jaya Manunggal Mandiri factory, some waste occurs, such as waste of movement because the distance between the production station is too far, etc. The new alternative layout was created using the S.L.P. Method to reduce the waste at all factory layouts. So the new alternative layout can increase the spring bed's production effectivity by decreasing the distance and production time. The new alternative layout can be seen in Figure 3.

Figure 3. New Alternative Layout

5. Results and Discussion

5.1 Numerical Results

Based on the observation performed 30 times at each operation on the spring beds production line, the cycle time can be found by using the average cycle time value from 30 times measurement. After the cycle time is obtained, the rating factor is needed to find the normal time. The rating factor can be found using the Westinghouse method. After getting the rating factor, the normal time for each process can be found by multiplying cycle time and rating factor. Then, the standard time can be found using the allowance from the normal time. The cycle time, rating factor, normal time, allowance, and standard time can be seen in Table 3.

Table 3. The Cycle Time, Rating Factor, Normal Time, Allowance, and Standard Time

Number	Operation	Cycle Time	Rating Factor	Normal Time	Allowance (%)	Standard Time
1	O-1	2.7	1.11	2.99	14	3.41
2	O-2	3.85	1.09	4.2	20	4.78
3	O-3	9.43	1.09	10.28	20	11.72
4	I-1	1.06	1.09	1.16	18	1.32
5	O-4	6.77	1.10	7.45	21	8.49
6	O-5 & I-2	1.34	1.09	1.46	18	1.66
7	O-6	1.66	1.09	1.81	18	2.06
8	I-3	1.3	1.09	1.42	18	1.62
9	O-7	1	1.11	1.11	14	1.27
10	O-8	3.47	1.09	3.78	20	4.31
11	I-4	1.35	1.09	1.47	18	1.68
12	O-9	8.21	1.10	9.03	21	10.29
13	O-10	7.13	1.07	7.63	22	8.7
14	O-11	8.92	1.07	9.54	22	10.88
15	O-12 & I-5	9.35	1.09	10.19	18	11.62
16	O-13	9.48	1.09	10.33	20	11.78
17	O-14	1.34	1.09	1.46	18	1.66
18	O-15	1.54	1.09	1.68	18	1.92
19	I-6	0.753	1.09	0.82	18	0.94
20	O-16	9.59	1.09	10.45	18	11.91
21	I-7	0.657	1.09	0.72	18	0.82
22	O-17	27.4	1.09	29.87	20	34.05
23	I-8	1.76	1.09	1.92	18	2.19
24	O-18	3.49	1.11	3.87	18	4.41

The total cycle time for the spring bed production process is 123.55 minutes, the total normal time for spring bed production is 133.64 minutes, and the total standard time for spring bed production is 153.49 minutes.

5.2 Set-up Time Comparison Before SMED and After SMED

After implementing single minutes exchange of dies, there is a decrease in set-up time in the spring beds production process. The comparison of the set-up time of spring bed production before implementation of SMED and after the performance of SMED can be seen in Table 4.

Table 4. Comparison of Set-up Time Before SMED and After SMED

Comparison	Before SMED (second)	After SMED (second)
Internal Activity	710	434
External Activity	0	165
Eliminated Activity	0	111

Before doing production, there is a set-up process in the spring beds production process. The SMED method is implemented to reduce set-up time by moving various activities that can be done without turning on the machine to external movements and eliminating activities that can be done before the production process. Spring beds set-up activity conversion can be seen in Table 5.

Before implementing SMED, all set-up activities are classified as internal activities, which causes the set-up time in the production process to take quite a bit of time. After the implementation of SMED, there is some activity converted into an external activity such as taking the raw material from the raw material storage, etc. By converting some internal activities to external activities, the set-up time for the spring beds production process was reduced by 165 seconds, decreasing the set-up time by 23.23%. Then, from the implementation of SMED, some set-up activity has been eliminated because the set-up activity can be done before the production process starts, such as taking the gauge from the auxiliary materials warehouse, etc. The set-up time from eliminating some set-up activity was reduced by 111 seconds, which decreased by 15.63%. From the implementation of SMED, the total set-up time was reduced from 710 seconds to 434 seconds which reduced the set-up time by 38.86%.

Table 5. Spring beds Set-up Activities Conversion

Process	Activity	Time (seconds)	Internal	External

Total Time (Second)		710	434	165

5.3 New Process Activity Mapping

The new process activity mapping was made from the new alternative layout. The distance and production time have been reduced by using the new layout. Some non-value-added activity has been eliminated, so the processing time of spring bed production becomes more efficient. The new process activity mapping for alternative layout 1 with eliminating the non-value-added activity can be seen in Table 6. The process activity mapping for alternative layout 2 with eliminating the non-value-added activities can be seen in Table 7.

Table 6. New Process Activity Mapping for Alternative Layout 1

Process	Activity Description	Machine/Tool	Distance (m)	Time (seconds)	Number of Workers	O	I	T	D	S

The comparison of the new process activity mapping for the old layout, alternative layout 1, and alternative layout 2 can be seen in Table 8.

Table 8. Comparison of Old Layout, Alternative Layout 1, and Alternative Layout 2

Comparison	Old Layout	Alternative Layout 1	Alternative Layout 2
Total Activity	41	36	36
Operation Time	9410 seconds	8704 seconds	8568 seconds
Distance	85 meters	44.5 meters	36.75 meters

After eliminating the non-value-added activity after waste analysis, the total activity of the process activity mapping for the alternative layout 1 and alternative layout 2 decreased from 41 activities to 36 activities which decreased by 12.2%. The total operation time of the old layout was 9410 seconds by implementing waste analysis and creating the new layout. The total operation time was decreased. The total operation time for alternative layout 1 is 8704 seconds and the total operation time for alternative layout 2 is 8568 seconds. The total distance of the old layout was 85 meters by implementing waste analysis and creating a new layout. The total distance was decreased. The total distance for alternative layout 1 is 44.5 meters and the total distance for alternative layout 2 is 36.75 meters. From the process activity mapping, the alternative layout 2 has the least total operation time of 8568 seconds. The reduction of total operation time by 8.95% and had the least distance of 36.75 meters. The new distance reduction of the spring beds production process by 56.77%. So the new alternative layout 2 was chosen to become the new layout for P.T. Alpha Jaya Manunggal Mandiri.

5.4 Value Stream Mapping

Value stream mapping is a lean manufacturing tool that helps us to understand the flow of materials and information in a process. Value stream mapping includes all value-adding and non-value-adding activities required to process a product from raw materials to delivery to customers. The current value stream mapping of the spring bed production process can be seen in Figure 4.

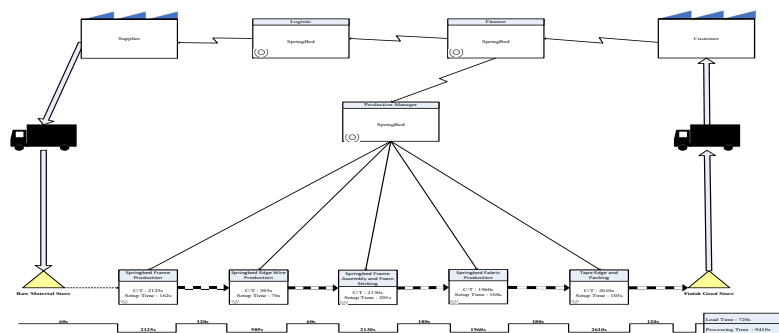

Figure 4. Current Value Stream Mapping

Future value stream mapping is made based on the alternative layout that has been chosen, which is the alternative layout 2. Future value stream mapping contains a series of process orders entering the company, then ordering materials and receiving the raw material warehouse until it reaches the customer. The future value stream mapping can be seen in Figure 5.

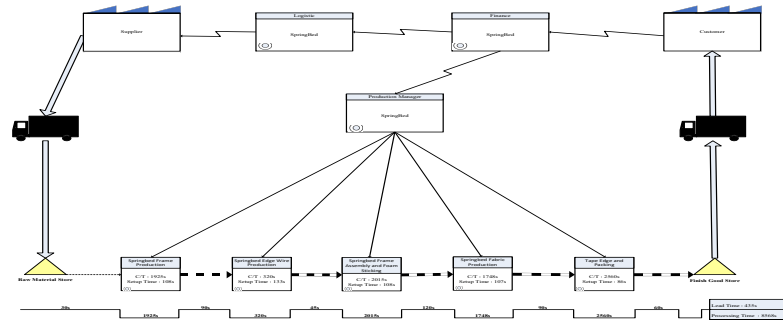

Figure 5. Future Value Stream Mapping

The efficiency between current value stream mapping and future value stream mapping can be seen in Table 9.

Table 9. Value Stream Mapping Efficiency

Operation	Standard Time CSVM	Standard Time FSVM	Reduction Percentage (%)
Spring beds Frame Production	2125 seconds	1925 seconds	9.58
Spring beds Edge Wire Production	585 seconds	320 seconds	45.3
Spring beds Frame Assembly and Foam Sticking	2130 seconds	2015 seconds	5.4
Spring beds Fabric Production	1960 seconds	1748 seconds	10.82
Tape Edge and Packing	2610 seconds	2560 seconds	0.2

The percentage of standard time between current value stream mapping and future value stream mapping on operation spring beds frame production reduced by 9.58%, on spring beds edge wire production reduced by 45.3%, on spring beds frame assembly and foam sticking reduced by 5.4%; on spring beds fabric production reduced by 10.82%; and on tape edge and packing reduced by 0.2%.

5.5 Proposed Improvement

Based on this research, the implementing SMED method on the spring beds set-up process, eliminating non-value-added processes and implementing the new layout could decrease spring beds set-up, lead time, distance, and production time. The comparison between the old layout and the new layout can be seen in Table 10.

Table 10. The Comparison Between New Layout and Old Layout

Comparison	Old Layout	New Layout	Percentage
Set-up Time	710 seconds	434 seconds	- 38.86 %
Lead Time	720 seconds	435 seconds	- 39.58%
Distance	85 meters	36.75 meters	- 56.77%
Production Time	9410 seconds	8568 seconds	- 8.95%

The set-up time from the old layout is 710 seconds and from the new layout is 434 seconds, which decreased set-up time by 38.86%. The lead time from the old layout is 720 seconds and from the new layout is 435 seconds, which decreased lead time by 39.58%. The distance from the old layout is 85 meters and from the new layout is 36.75 meters, which reduced the distance by 56.77%. The production time from the old layout is 9410 seconds and from the new layout is 8568 seconds, which reduced production time by 8.95%.

5.6 Validation

From the 30 data collected, it is necessary to do a normality, uniformity, and adequacy test to determine whether the collected data is normal, uniform, and sufficient. The normality test was done using Software Minitab by using the Anderson-Darling method. If the P-value is greater than 0.05, then the collected data is normal. The uniformity tests were done by finding the U.C.L. and L.C.L. If the data distribution is not beyond the U.C.L. and L.C.L., then the collected data

is uniform. The adequacy test used a confident level of 95% and a significance level of 5%. If N is greater than N', the collected data is sufficient. From the normality test, all operations have a P-value greater than 0.05, so all the operation data collected were normal. All operation data ordered do not exceed U.C.L. and L.C.L. from the uniformity test, so the data collected were uniform. All the collected data is greater than N' from the adequacy test, so the data collected were sufficient.

6. Conclusion

From the waste analysis that has been done, there is 5 non-value-added activity in the spring beds production process. The non-value-added activity then will be eliminated to reduce spring bed production time. Then the new alternative layout was created by using Systematic Layout Planning (S.L.P.) Method. The new alternative layout has been made in 2 forms: alternative layout 1 and layout 2. From the alternative layout, the distance and operation time were decreased. The total activity of the process activity mapping for the alternative layout 1 and alternative layout 2 decreased from 41 activities to 36 activities which decreased by 12.2%. The total operation time of the old layout was 9410 seconds by implementing waste analysis and creating the new layout. The total operation time was reduced. The total operation time for alternative layout 1 is 8704 seconds and the total operation time for alternative layout 2 is 8568 seconds. The total distance of the old layout was 85 meters by implementing waste analysis and creating a new layout. The total distance was decreased. The total distance for alternative layout 1 is 44.5 meters and the total distance for alternative layout 2 is 36.75 meters. From the process activity mapping, the alternative layout 2 has the least total operation time of 8568 seconds, which decreased the total operation time by 8.95% and had the least distance of 36.75 meters, which reduced the distance of the spring beds production process by 56.77%. So alternative layout 2 was chosen to become the new layout for P.T. Alpha Jaya Manunggal Mandiri.

Before implementing SMED, the set-up activity total time was 710 seconds. Then after the implementation of SMED, there is some activity converted into an external activity, such as taking the raw material from the raw material storage, etc. By converting some internal activities to external activities, the set-up time for the spring beds production process was reduced by 165 seconds, decreasing the set-up time by 23.23%. Then, from the implementation of SMED, some set-up activity has been eliminated because the set-up activity can be done before the production process starts, such as taking the gauge from the auxiliary materials warehouse, etc. From the implementation of SMED, the total set-up time turned into 434 seconds which decreased the set-up time by 38.86%. From the value stream mapping, the efficiency between current value stream mapping and future value stream mapping on operation spring beds frame production is 90.58%; on spring beds edge wire production is 54.7%; on spring beds frame assembly and foam sticking is 94.6%; on spring beds fabric production is 89.18%; and on tape edge and packing is 99.8%. Also, the lead time after implementing the new layout decreased from 720 seconds to 435 seconds, which decreased lead time by 39.58%.

Biographies

Geraldo Rafael, was born in Jakarta, 27 December 2001 the capital city of Indonesia. In the present time, I am an ordinary third-year college student who studies at Tarumanagara University. I'm currently majoring in industrial engineering. I like to do some research about plant layout and lean six sigma.

Sherine Angellina Hoswari, an Industrial Engineering student at Tarumanagara University. I am an ordinary first-year college student who often participates in student activities. I like broadcasting and public speaking because that thing could increase my ability.

Natasia Aurellia, an Industrial Engineering student at Tarumanagara University. I am currently studying as a first-year student. I am a friendly, enthusiastic, and honest person. I am flexible to work at any time and any place. I am someone who loves to learn about new and challenging things.

Lina Gozali is a lecturer at the Industrial Engineering Department of Universitas Tarumangara since 2006 and a freelance lecturer at Universitas Trisakti since 1995. She graduated with her Bachelor's degree at Trisakti University, Jakarta - Indonesia, then she got her Master's Degree at STIE IBII, Jakarta – Indonesia, and she recently got her Ph.D. at Universiti Teknologi Malaysia, Kuala Lumpur – Malaysia in 2018. Her apprentice college experience was in paper industry at Kertas Bekasi Teguh, shoes industry at P.T. Jaya Harapan Barutama, and automotive chain drive industry at Federal Superior Chain Manufacturing. She teaches Production System and Supply Chain Management Subjects. She did a research about Indonesian Business Incubator for her Ph.D. She has written almost 70 publications since 2008 in the Industrial Engineering research sector, such as Production Scheduling, Plant Layout, Maintenance, Line Balancing, Supply Chain Management, Production Planning, and Inventory Control. She had worked at P.T. Astra Otoparts Tbk before she became a lecturer.

Ahad Ali is an Associate Professor and Director of Industrial Engineering Program in the A. Leon Linton Department of Mechanical, Robotics and Industrial Engineering at the Lawrence Technological University, Southfield, Michigan, U.S.A. He earned B.S. in Mechanical Engineering from Khulna University of Engineering and Technology, Bangladesh, Masters in Systems and Engineering Management from Nanyang Technological University, Singapore and PhD in Industrial Engineering from University of Wisconsin-Milwaukee. He has published journal and conference papers. Dr Ali has completed research projects with Chrysler, Ford, New Center Stamping, Whelan Co., Progressive Metal Manufacturing Company, Whitlam Label Company, DTE Energy, Delphi Automotive System, G.E. Medical Systems, Harley-Davidson Motor Company, International Truck and Engine Corporation (ITEC), National/Panasonic Electronics, and Rockwell Automation. His research interests include manufacturing, simulation, optimization, reliability, scheduling, manufacturing, and lean. He is member of IEOM, INFORMS, S.M.E. and IEEE.
